Marketing/editorial option 3 · Data security

Explaining DeepL’s data-security safeguards in plain language

I translated infrastructure, compliance and access-control details into a clear business article about sensitive translation data.

My role

Marketing writer for long-form B2B security content

Worked with

Security, legal, product marketing and editorial stakeholders

Why it mattered

Business readers needed specific explanations of how DeepL handled sensitive data.

01 · The article

Explaining security through specific product safeguards

The visual establishes protection; the article earns that promise by explaining the mechanisms behind it.

02 · The problem

Business readers needed specific explanations of how DeepL handled sensitive data.

Security content often collapses into certification lists and superlatives. That may sound authoritative, but it leaves a business reader to work out what the safeguards mean for the text, documents and account access they actually care about.

The article needed a usable hierarchy: why the subject matters, what DeepL does with customer data, how the service stays available, who can access information and how administrators control team access.

Constraint

The article needed to explain servers, data retention, encryption, failover, subcontractors and account controls accurately—without assuming a security specialist was reading.

03 · The language turn

Replace reassurance with behavior

04 · The judgment

The decisions doing the work

01

Organize around reader questions

Question-led sections move from the business risk to data handling, reliability, access and the

practical value of those safeguards.

02

Translate the mechanism

TLS, failover and least privilege retain their technical names, then receive a plain-language explanation of the behavior they create.

03

Make data handling specific

Temporary processing, deletion after translation and model-training boundaries give the reader concrete statements to evaluate.

04

Use expert voices as evidence

Legal perspectives from Taylor Wessing add context about EU data handling rather than replacing the product explanation.

The trade-off: Technical specificity makes the article longer, but removing the mechanisms would turn a security explanation into a set of claims the reader simply has to trust.

05 - The explanation

The metaphor is supported by a clear data-handling statement

The illustration reinforces the accompanying explanation that Pro text is processed for translation and then deleted.

06 - The outcome

What the work made possible

The article turns a broad trust proposition into an inspectable security story spanning data centers, text handling, encrypted transmission, reliability, third-party access and team administration.

What this shows

This is a historical editorial example published in May 2023. The portfolio preserves the article's original claims; current technical and product details should be rechecked before publication.
